Overview

This project includes 3 time series dataset and requires to select best forecasting model for all 3 datasets.

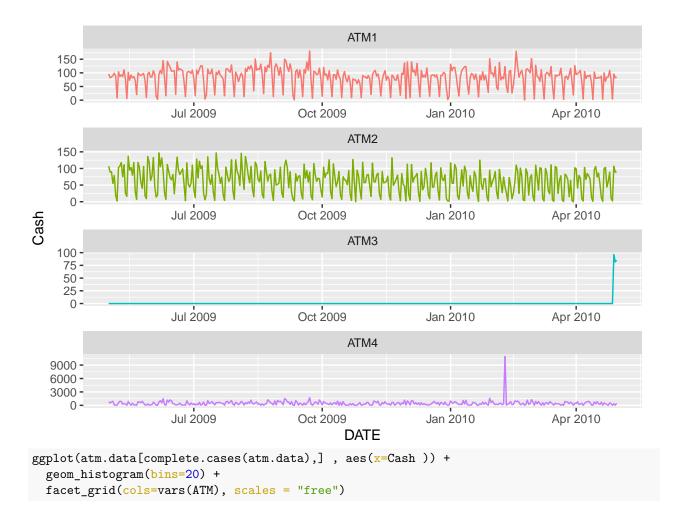

- Part A ATM Forecast
- Part B Forecasting Power
- Part C Waterflow Pipe

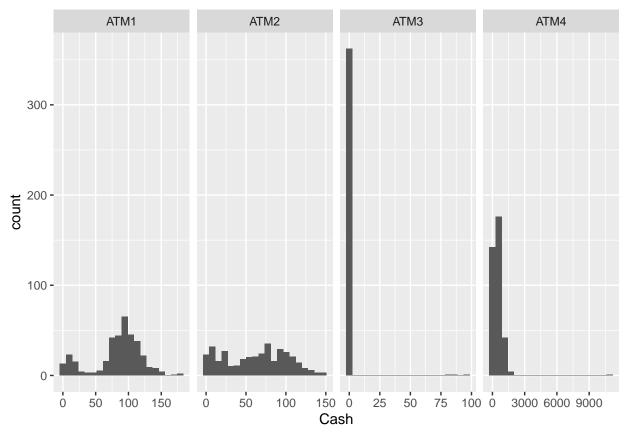

Part A - ATM Forecast

The dataset contains cash withdrawals from 4 different ATM machines from May 2009 to Apr 2010. The variable 'Cash' is provided in hundreds of dollars and data is in a single file. Before starting our analysis we will first download the excel from github and then read it through read_excel.

Exploratory Analysis

```
quiet = TRUE)
atm.data <- read_excel(temp.file, skip=0, col_types = c("date", "text", "numeric"))
glimpse(atm.data)

Per above exploratory analysis, all ATMs show different patterns. We would perform forecasting for each

ATM separately.

- ATM1 and ATM2 shows similar pattern (approx.) throughout the time. ATM1 and ATM2 have 3 and 2 missing entries respectively.
- ATM3 appears to become online in last 3 days only and rest of days appears inactive. So the data available for this ATM is very limited.
- ATM4 requires replacement for outlier and we can assume that one day spike of cash withdrawal is unique. It has an outlier showing withdrawl amount 10920.

Data Cleaning

For this part we will first apply ts() function to get required time series. Next step is to apply tsclean function that will handle missing data along with outliers. To estimate missing values and outlier replacements, this function uses linear interpolation on the (possibly seasonally adjusted) series. Once we get the clean data we will use pivot longer to get the dataframe in its original form.

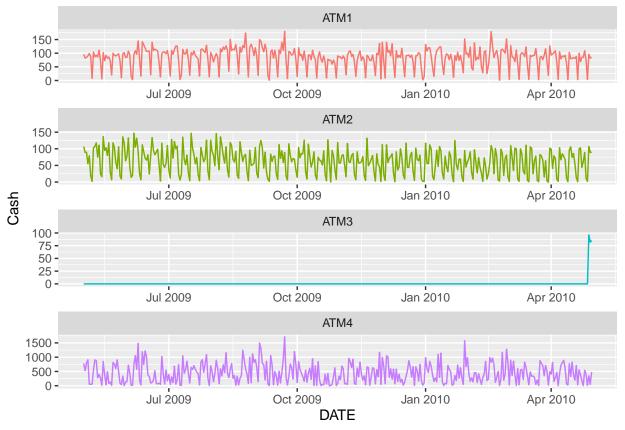

```
atm.ts <- ts(atm.comp %>% select(-DATE))
head(atm.ts)

##
    3rd Qu.:108.00
   Max.
           :180.00
                      Max.
                             :147.00
                                       Max.
                                               :96.0000
                                                          Max.
                                                                  :1712.075
```

If we compare this summary with previous one of original data, ATM1 and ATM2 has nomore NAs and ATM4 outlier value (10919.762) is handled and now the max value is 1712.075.

```
## DATE ATM Cash
## 1 2009-05-01 ATM1 96
```

```
## 2 2009-05-02 ATM1 82
## 3 2009-05-03 ATM1 85
## 4 2009-05-04 ATM1 90
## 5 2009-05-05 ATM1 99
## 6 2009-05-06 ATM1 88
ggplot(atm.new , aes(x=DATE, y=Cash, col=ATM)) +
   geom_line(show.legend = FALSE) +
   facet_wrap(~ATM, ncol=1, scales = "free")
```

Though above plot doesn't show much differences for ATM1,2,3 but tsclean handled the ATM4 data very well after replacing the outlier.

Time Series

Function to plot forecast for various models.

```
# function to plot forecast(s)
atm.forecast <- function(timeseries) {
    # lambda value
    lambda <- BoxCox.lambda(timeseries)
    # models for forecast
    hw.model <- timeseries %>% hw(h=31, seasonal = "additive", lambda = lambda, damped = TRUE)
    ets.model <- timeseries %>% ets(lambda = lambda)
    arima.model <- timeseries %>% auto.arima(lambda = lambda)
    # forecast
    atm.hw.fcst <- forecast(hw.model, h=31)
    atm.ets.fcst <- forecast(ets.model, h=31)
    atm.arima.fcst <- forecast(arima.model, h=31)</pre>
```

```
# plot forecasts
p1 <- autoplot(timeseries) +
   autolayer(atm.hw.fcst, PI=FALSE, series="Holt-Winters") +
   autolayer(atm.ets.fcst, PI=FALSE, series="ETS") +
   autolayer(atm.arima.fcst, PI=FALSE, series="ARIMA") +
   theme(legend.position = "top") +
   ylab("Cash Withdrawl")
# zoom in plot
p2 <- p1 +
   labs(title = "Zoom in ") +
   xlim(c(51,56))
grid.arrange(p1,p2,ncol=1)
}</pre>
```

Function to calculate RMSEs for various models.

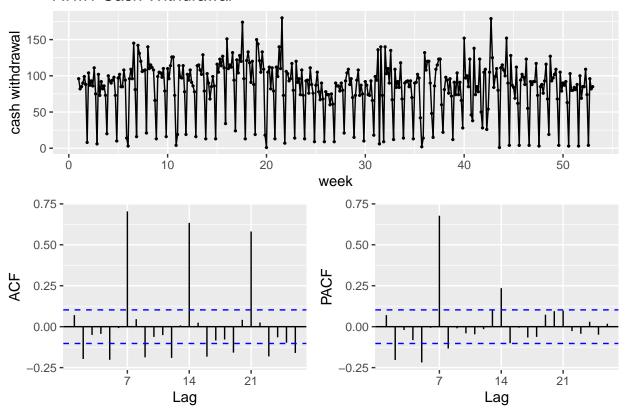

```
model_accuracy <- function(timeseries, atm_num) {</pre>
  # lambda value
  lambda <- BoxCox.lambda(timeseries)</pre>
  # split the data to train and test
  train <- window(timeseries, end=c(40, 3))</pre>
  test <- window(timeseries, start=c(40, 4))</pre>
  # models for forecast
  hw.model <- train %>% hw(h=length(train), seasonal = "additive", lambda = lambda, damped = TRUE)
  ets.model <- train %>% ets(model='ANA', lambda = lambda)
  # Arima model
  if (atm_num == 1) {
    # for ATM1
    arima.model <- train %>% Arima(order=c(0,0,2),
                                         seasonal = c(0,1,1),
                                         lambda = lambda)
  } else if(atm_num == 2) {
    # for ATM2
    arima.model <- train %>% Arima(order=c(3,0,3),
                                         seasonal = c(0,1,1),
                                         include.drift = TRUE,
                                         lambda = lambda,
                                         biasadj = TRUE)
  } else {
    # for ATM4
    arima.model <- train %>% Arima(order=c(0,0,1),
                                     seasonal = c(2,0,0),
                                     lambda = lambda)
  }
  # forecast
  hw.frct = forecast(hw.model, h = length(test))$mean
  ets.frct = forecast(ets.model, h = length(test))$mean
  arima.frct = forecast(arima.model, h = length(test))$mean
```

ATM1

Seeing the time series plot, it is clear that there is a seasonality in the data. We can see increasing and decreasing activities over the weeks in below plot. From the ACF plot, we can see a slight decrease in every 7th lag due to trend. PACF plot shows some significant lags at the beginning.

```
atm1.ts <- atm.new %>% filter(ATM=="ATM1") %>% select(Cash) %>% ts(frequency = 7)
ggtsdisplay(atm1.ts, main="ATM1 Cash Withdrawal", ylab="cash withdrawal", xlab="week")
```

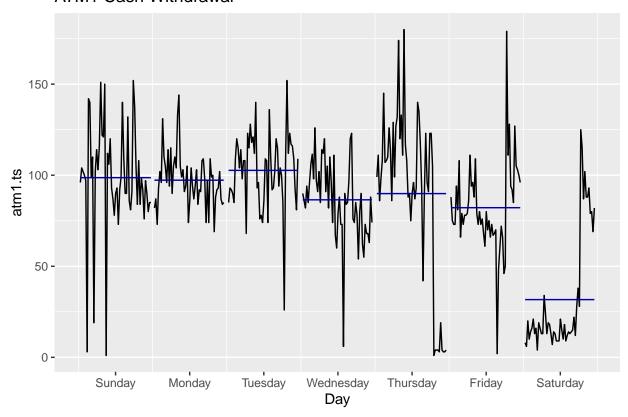

From the above plots it is evident that the time series is non stationary, showing seasonality and will require differencing to make it stationary.

```
ggsubseriesplot(atm1.ts, main="ATM1 Cash Withdrawal")
```

ATM1 Cash Withdrawal

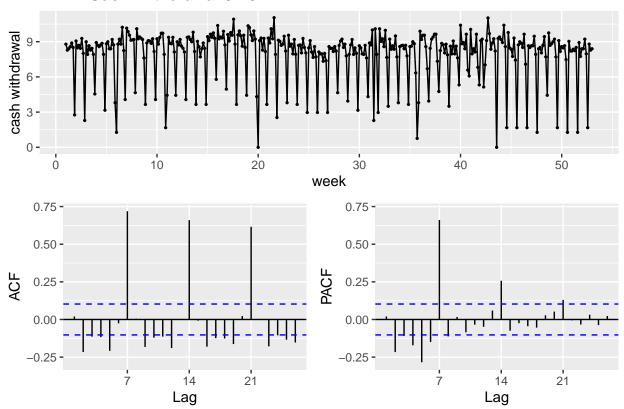

From the subseries plot, it is apparent that Tuesdays having highest mean of ash withdrawl while Saturdays being the lowest.

Next step is to apply BoxCox transformation. With λ being 0.26, the resulting transformation does handle the variablity in time series as shown in below transformed plot.

```
atm1.lambda <- BoxCox.lambda(atm1.ts)
atm1.ts.bc <- BoxCox(atm1.ts, atm1.lambda)
ggtsdisplay(atm1.ts.bc, main=paste("ATM1 Cash Withdrawal",round(atm1.lambda, 3)), ylab="cash withdrawal"</pre>
```

ATM1 Cash Withdrawal 0.262

Next we will see the number of differences required for a stationary series and the number of differences required for a seasonally stationary series.

```
# Number of differences required for a stationary series
ndiffs(atm1.ts.bc)
```

[1] 0

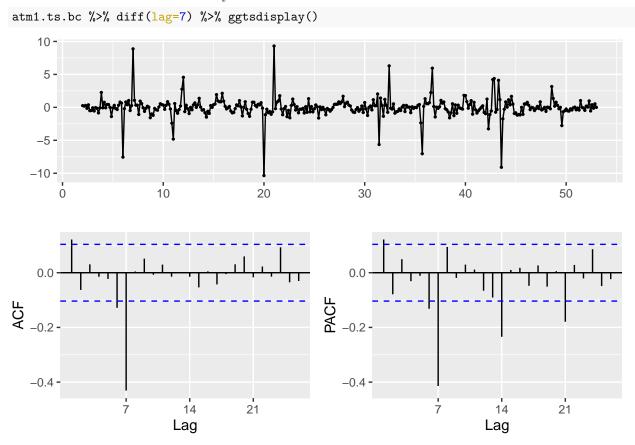

```
# Number of differences required for a seasonally stationary series nsdiffs(atm1.ts.bc)
```

[1] 1

It shows number of differences required for a seasonality stationary series is 1. Next step is to check kpss summary.

```
atm1.ts.bc %>% diff(lag=7) %>% ur.kpss() %>% summary()
```

We can see the test statistic small and well within the range we would expect for stationary data. So we can conclude that the data are stationary.

The data is non-stationary with seasonality so there will be a seasonal difference of 1. Finally, the differencing of the data has now made it stationary. From the ACF plot, it is apparent now that there is a significant spike at lag 7 but none beyond lag 7.

Lets start with Holt-Winter's additive model with damped trend since the seasonal variations are roughly constant through out the series.

```
# Holt Winters with damped True
atm1.ts %>% hw(h=31, seasonal = "additive", lambda = atm1.lambda, damped = TRUE)
##

## 57.42857
```

Next is to apply exponential smoothing method on this time series. It shows that the ETS(A, N, A) model best fits for the transformed ATM4, i.e. exponential smoothing with additive error, no trend component and additive seasonality.

```
atm1.ts %>% ets(lambda = atm1.lambda )

## ETS(A,N,A)
##
## Call:
## ets(y = ... lambda = atm1.lambda)
```

```
##
    ets(y = ., lambda = atm1.lambda)
##
     Box-Cox transformation: lambda= 0.2616
##
##
##
     Smoothing parameters:
##
       alpha = 1e-04
##
       gamma = 0.3513
##
##
     Initial states:
##
       1 = 7.9717
##
       s = -4.5094 \ 0.5635 \ 1.0854 \ 0.5711 \ 0.9551 \ 0.5582
##
##
##
     sigma:
              1.343
##
##
        AIC
                 AICc
                             BIC
```

2379.653 2380.275 2418.652

Next we will find out the appropriate ARIMA model for this time series. The suggested model seems ARIMA(0,0,2)(0,1,1)[7].

```
atm1.fit3 <- atm1.ts %>% auto.arima(lambda = atm1.lambda)
atm1.fit3

## Series: .
## ARIMA(0,0,2)(0,1,1)[7]
## Box Cox transformation: lambda= 0.2615708
##
## Coefficients:
## ma1 ma2 sma1
```

```
## 0.1126 -0.1094 -0.6418

## s.e. 0.0524 0.0520 0.0432

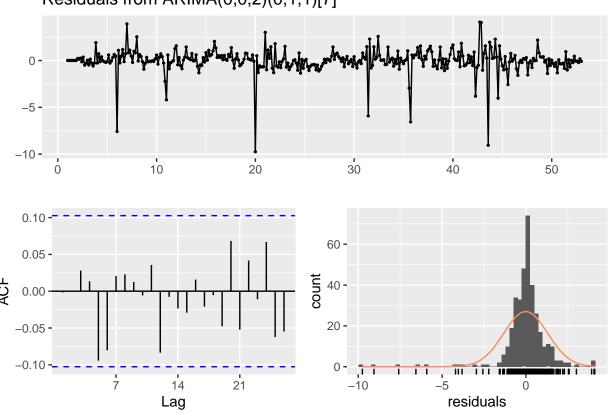

##

## sigma^2 estimated as 1.764: log likelihood=-609.99

## AIC=1227.98 AICc=1228.09 BIC=1243.5
```

Next is to see residuals time series plot which shows residuals are being near normal with mean of the residuals being near to zero. Also there is no significant autocorrelation that confirms that forecasts are good. checkresiduals(atm1.fit3)

Residuals from ARIMA(0,0,2)(0,1,1)[7]

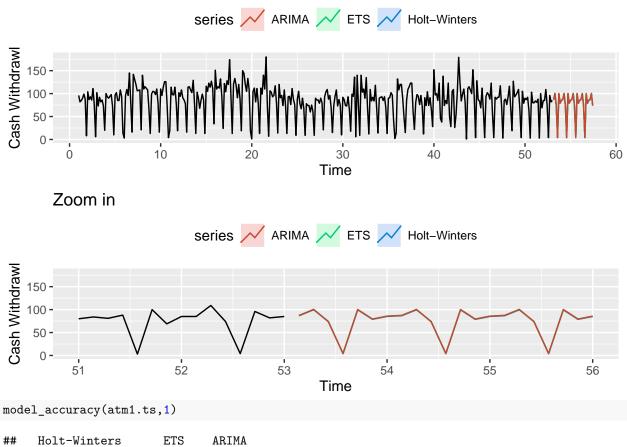

```
##
## Ljung-Box test
##
## data: Residuals from ARIMA(0,0,2)(0,1,1)[7]
## Q* = 9.8626, df = 11, p-value = 0.5428
##
## Model df: 3. Total lags used: 14
```

Let's plot the forecast for all the considered models above which will shows a nice visual comparison. it will also show a zoomed in plot to have a clearer view.

```
atm.forecast(atm1.ts)
```

```
\#\# Scale for 'x' is already present. Adding another scale for 'x', which will \#\# replace the existing scale.
```

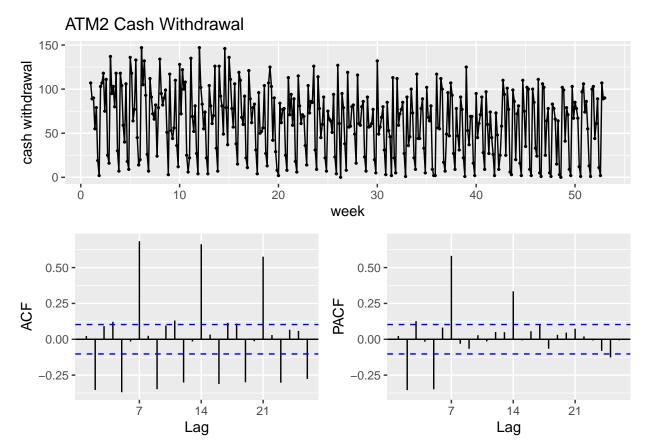

1 49.35115 49.22521 49.18074

ATM2

From the time series plot, it is apparent that there is a seasonality in the data but dont see a trend over the period. ACF shows teh significant lags at 7,14 and 21 confirming seasonality. From the PACF, there are few significant lags at the beginning but others within critical limit. Overall, it is non stationary, having seasonality and would require differencing for it to become stationary.

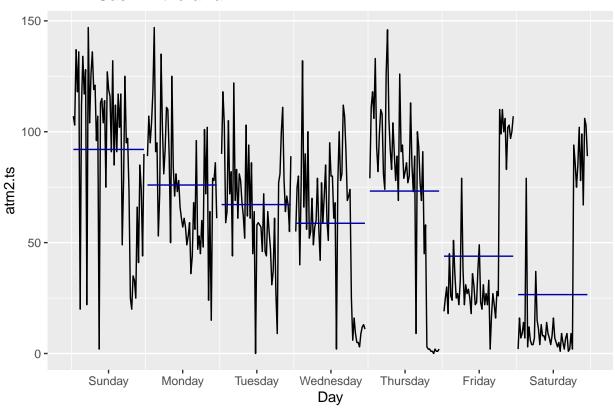

```
atm2.ts <- atm.new %>% filter(ATM=="ATM2") %>% select(Cash) %>% ts(frequency = 7) ggtsdisplay(atm2.ts, main="ATM2 Cash Withdrawal", ylab="cash withdrawal", xlab="week")
```

From the subseries plot, it is clear that Sunday is having highest mean for cash withdrawl while Saturday has the lowest.

ggsubseriesplot(atm2.ts, main="ATM2 Cash Withdrawal")

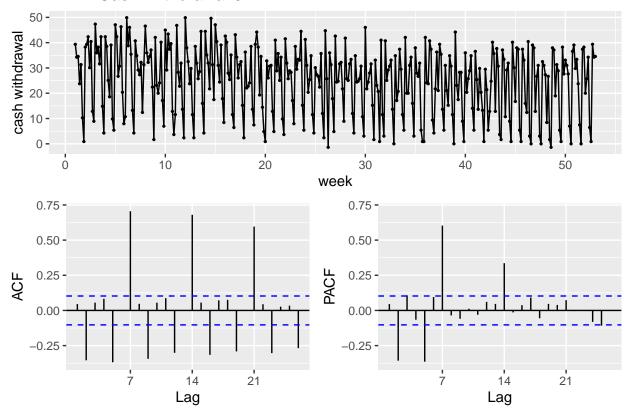

ATM2 Cash Withdrawal

Next step is to apply BoxCox transformation. With λ being 0.72, the resulting transformation does handle the variablity in time series as shown in below transformed plot.

```
atm2.lambda <- BoxCox.lambda(atm2.ts)
atm2.ts.bc <- BoxCox(atm2.ts, atm2.lambda)
ggtsdisplay(atm2.ts.bc, main=paste("ATM2 Cash Withdrawal",round(atm2.lambda, 3)), ylab="cash withdrawal"</pre>
```

ATM2 Cash Withdrawal 0.724

Number of differences required for a stationary series
ndiffs(atm2.ts.bc)

[1] 1

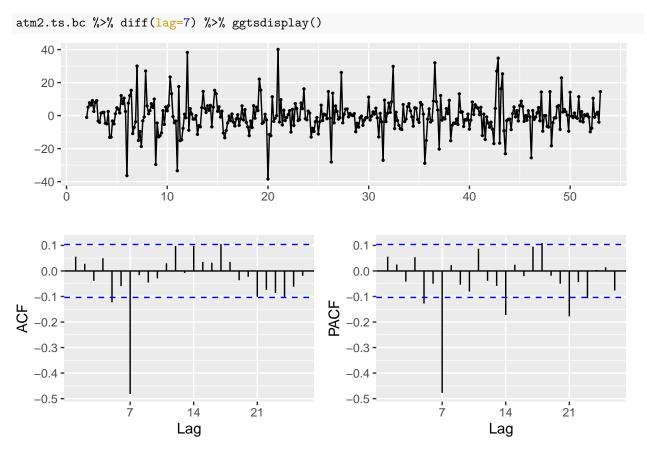

```
# Number of differences required for a seasonally stationary series nsdiffs(atm2.ts.bc)
```

[1] 1

It shows number of differences required is 1 for boxcox transformed data.

```
atm2.ts.bc %>% diff(lag=7) %>% ur.kpss() %>% summary()
```

We can see the test statistic small and well within the range we would expect for stationary data. So we can conclude that the data are stationary

First we will start with Holt-Winters damped method. Damping is possible with both additive and multiplicative Holt-Winters' methods. This method often provides accurate and robust forecasts for seasonal data is the Holt-Winters method with a damped trend.

```
# Holt Winters
atm2.ts %>% hw(h=31, seasonal = "additive", lambda = atm2.lambda, damped = TRUE)
## Point Forecast Lo 80 Hi 80 Lo 95 Hi 95
```

```

Next is to apply exponential smoothing method on this time series. It shows that the ETS(A, N, A) model best fits for the transformed ATM4, i.e. exponential smoothing with additive error, no trend component and additive seasonality.

```
atm2.ts %>% ets(lambda = atm2.lambda)
## ETS(A,N,A)
##
## Call:
##
    ets(y = ., lambda = atm2.lambda)
##
##
     Box-Cox transformation: lambda= 0.7243
##
##
     Smoothing parameters:
##
       alpha = 1e-04
##
       gamma = 0.3852
##
##
     Initial states:
##
       1 = 26.7912
##
       s = -17.8422 - 13.3191 \ 10.8227 \ 1.8426 \ 4.2781 \ 5.7994
##

                                                                         0.0072
##
## sigma^2 estimated as 67.52: log likelihood=-1260.59
```

AIC=2539.18 AICc=2539.69 BIC=2574.1

Next is to see residuals time series plot which shows residuals are being near normal with mean of the residuals being near to zero. Also there is no significant autocorrelation that confirms that forecasts are good. checkresiduals(atm2.fit3)

Residuals from ARIMA(3,0,3)(0,1,1)[7] with drift

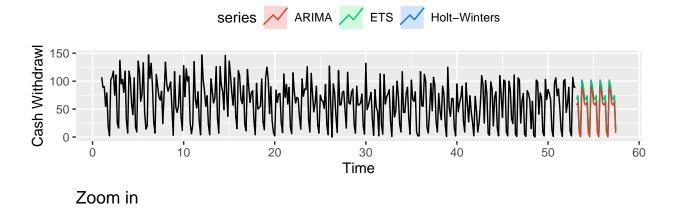

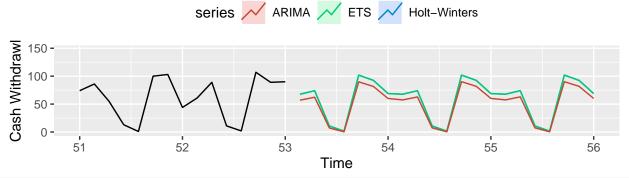

```
##
## Ljung-Box test
##
## data: Residuals from ARIMA(3,0,3)(0,1,1)[7] with drift
## Q* = 8.944, df = 6, p-value = 0.1768
##
## Model df: 8. Total lags used: 14
```

Next step is to plot the forecast for all the considered models above which will shows a nice visual comparison. it will also show a zoomed in plot to have a clearer view.

```
atm.forecast(atm2.ts)
```

Scale for 'x' is already present. Adding another scale for 'x', which will ## replace the existing scale.

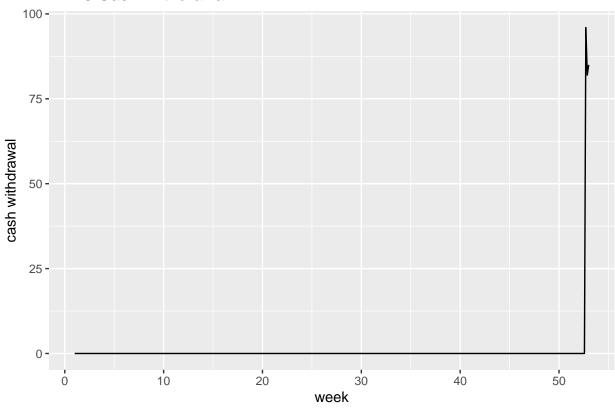

model_accuracy(atm2.ts,2)

Holt-Winters ETS ARIMA ## 1 57.20467 57.58101 56.58658

ATM3

atm3.ts <- atm.new %>% filter(ATM=="ATM3") %>% select(Cash) %>% ts(frequency = 7) autoplot(atm3.ts, main="ATM3 Cash Withdrawal", ylab="cash withdrawal", xlab="week")

ATM3 Cash Withdrawal

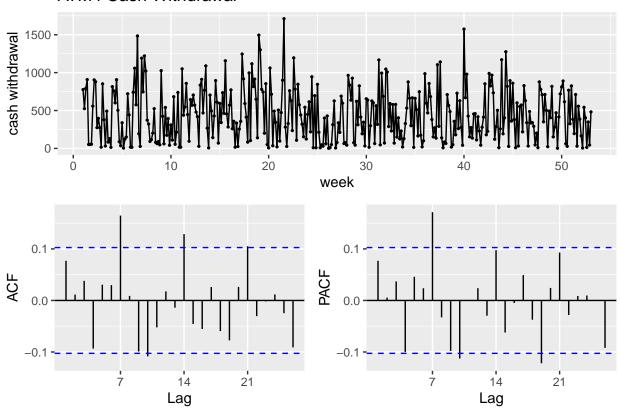

ATM4

Seeing the time series plot, it is apparent that there is seasonality in this series. ACF shows a decrease in every 7th lag. From the PACF, there are few significant lags at the beginning but others within critical limit. Overall, it is non stationary, having seasonality and might require differencing for it to become stationary.

```
atm4.ts <- atm.new %>% filter(ATM=="ATM4") %>% select(Cash) %>% ts(frequency = 7) ggtsdisplay(atm4.ts, main="ATM4 Cash Withdrawal", ylab="cash withdrawal", xlab="week")
```

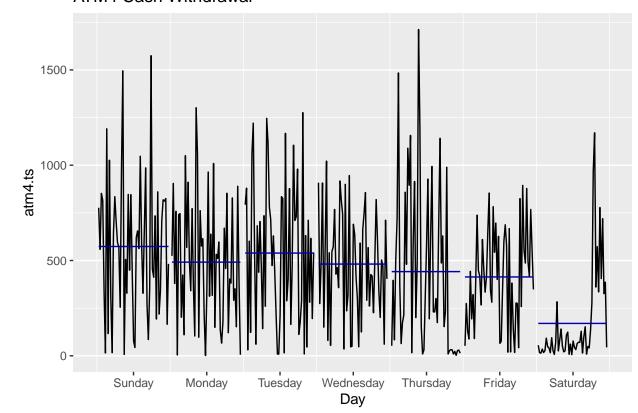

From the subseries plot, it is clear that Sunday is having highest mean for cash withdrawl while Saturday has the lowest.

ggsubseriesplot(atm4.ts, main="ATM4 Cash Withdrawal")

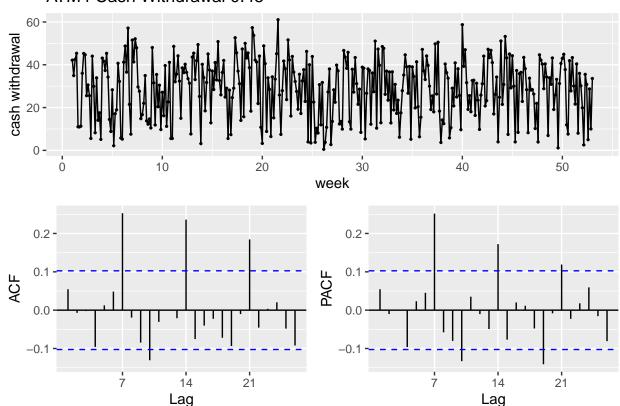

ATM4 Cash Withdrawal

Next step is to apply BoxCox transformation. With λ being 0.45, the resulting transformation does handle the variablity in time series as shown in below transformed plot.

```
atm4.lambda <- BoxCox.lambda(atm4.ts)
atm4.ts.bc <- BoxCox(atm4.ts, atm4.lambda)
ggtsdisplay(atm4.ts.bc, main=paste("ATM4 Cash Withdrawal",round(atm4.lambda, 3)), ylab="cash withdrawal"</pre>
```

ATM4 Cash Withdrawal 0.45

Number of differences required for a stationary series
ndiffs(atm4.ts.bc)

[1] 0

```
# Number of differences required for a seasonally stationary series nsdiffs(atm4.ts.bc)
```

[1] 0

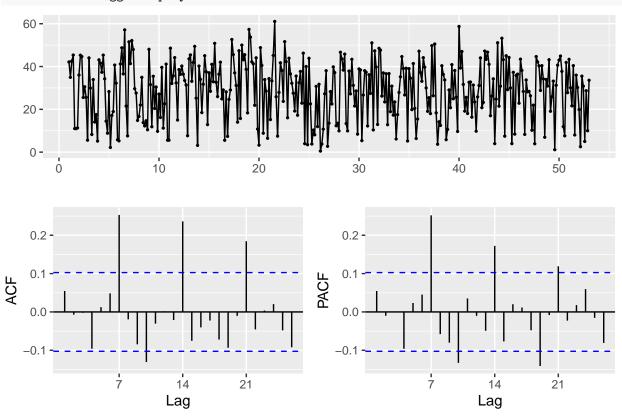

It shows number of differences required is 0 for boxcox transformed data.

atm4.ts.bc %>% ur.kpss() %>% summary()

```
##
  #############################
  # KPSS Unit Root Test #
##
  ########################
##
## Test is of type: mu with 5 lags.
##
  Value of test-statistic is: 0.0792
##
##
##
  Critical value for a significance level of:
##
                    10pct 5pct 2.5pct 1pct
## critical values 0.347 0.463 0.574 0.739
```

We can see the test statistic small and well within the range we would expect for stationary data. So we can conclude that the data are stationary.

First we will start with Holt-Winters damped method. Damping is possible with both additive and multiplicative Holt-Winters' methods. This method often provides accurate and robust forecasts for seasonal data is the Holt-Winters method with a damped trend.

```
# Holt Winters
atm4.ts %>% hw(h=31, seasonal = "additive", lambda = atm4.lambda, damped = TRUE)
```

```

```

Next is to apply exponential smoothing method on this time series. It shows that the ETS(A, N, A) model best fits for the transformed ATM4, i.e. exponential smoothing with additive error, no trend component and additive seasonality.

```
atm4.ts %>% ets(lambda = atm4.lambda)
## ETS(A,N,A)
##
## Call:
##
    ets(y = ., lambda = atm4.lambda)
##
##
     Box-Cox transformation: lambda= 0.4498
##
##
     Smoothing parameters:
##
       alpha = 1e-04
##
       gamma = 0.1035
##
##
     Initial states:
##
       1 = 28.6369
##
       s = -18.6503 - 3.3529 1.6831 4.7437 5.4471 4.9022
##
              5.2271
##
##
     sigma: 12.9202
##
##
                 AICc
                           BIC
        AIC
## 4032.268 4032.890 4071.267
```

Next we will find out the appropriate ARIMA model for this time series. The suggested model seeems ARIMA(0,0,1)(2,0,0)[7] with non-zero mean.

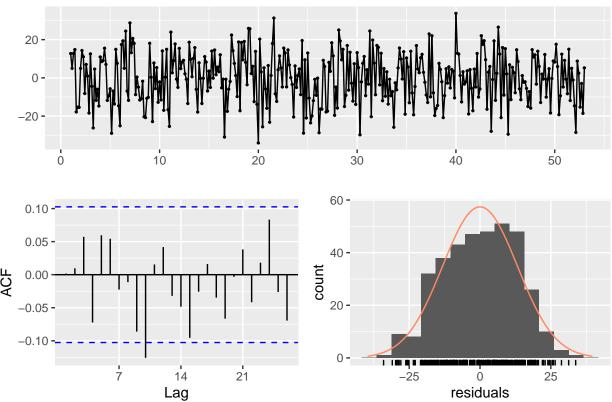

```
atm4.fit3 <- atm4.ts %>% auto.arima(lambda = atm4.lambda)
atm4.fit3
## Series: .
## ARIMA(0,0,1)(2,0,0)[7] with non-zero mean
## Box Cox transformation: lambda= 0.449771
##
## Coefficients:
##
            ma1
                   sar1
                            sar2
                                     mean
##
         0.0790
                 0.2078
                         0.2023
                                  28.6364

                         0.0525
                                   1.2405
##
```

```
## sigma^2 estimated as 176.5: log likelihood=-1460.57
## AIC=2931.14 AICc=2931.3 BIC=2950.64
```

Next is to see residuals time series plot which shows residuals are being near normal with mean of the residuals being near to zero. Also there is no significant autocorrelation that confirms that forecasts are good.

checkresiduals(atm4.fit3)

```
##
## Ljung-Box test
```

data: Residuals from ARIMA(0,0,1)(2,0,0)[7] with non-zero mean

Q* = 16.645, df = 10, p-value = 0.0826

##

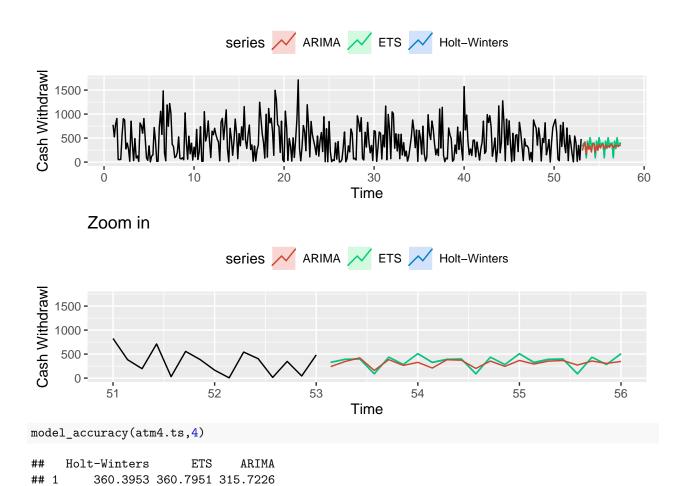

##

Model df: 4. Total lags used: 14

Next is to plot the forecast for all the considered models above which will shows a nice visual comparison. it will also show a zoomed in plot to have a clearer view.

```
atm.forecast(atm4.ts)
```

Scale for 'x' is already present. Adding another scale for 'x', which will ## replace the existing scale.

Forecast May, 2010

# Number of differences required for a stationary series
ndiffs(power.ts.bc)
## [1] 1
# Number of differences required for a seasonally stationary series
nsdiffs(power.ts.bc)
```

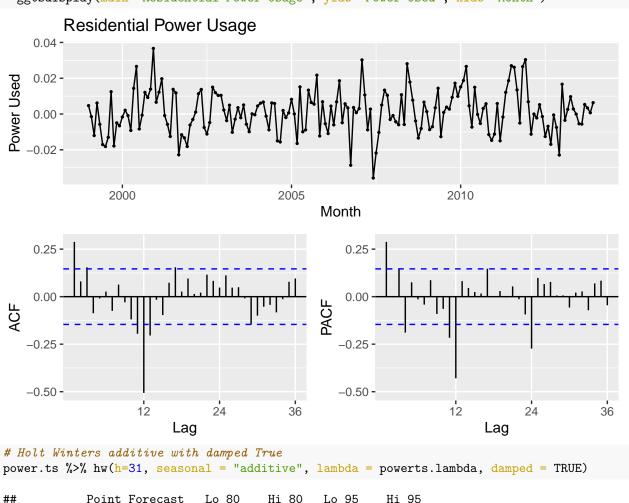

[1] 1

It shows number of differences required is 1 for boxcox transformed data.

```
power.ts.bc %>% diff(lag=12) %>% ur.kpss() %>% summary()
```

We can see the test statistic small and well within the range we would expect for stationary data. So we can conclude that the data are stationary.

```
power.ts.bc %>%
  diff(lag=12) %>%
  ggtsdisplay(main="Residential Power Usage", ylab="Power Used", xlab="Month")
```

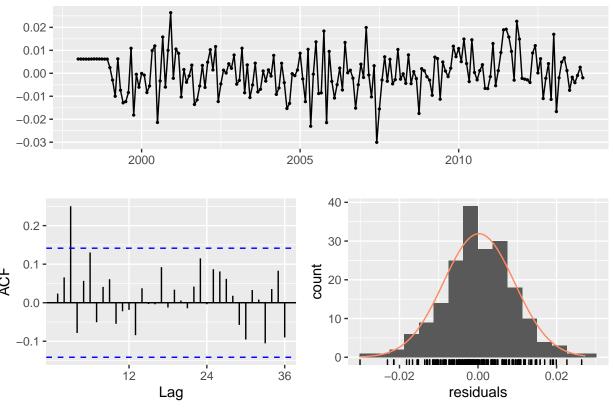

```

```
kable_paper() %>%
scroll_box(width = "500px", height = "200px")
```

Exploratory Analysis

It is apparent here that the data is recorded on different time intervals for pipe1 and pipe2. For pipe1 it shows records for multiple time intervals within an hour i.e. not evenly distributed while for pipe2 it seems hourly recorded. We can check the daily frequency count below for both datasets to confirm this finding.

```
p1 <- pipe1.data
p1$Date <- ymd_hms(p1$`Date Time`)
p1$Date <- as.Date(p1$Date)

p1 <- p1 %>% group_by(Date) %>% summarise("Pipe1 Records count"=n())

p2 <- pipe2.data
p2$Date <- ymd_hms(p2$`Date Time`)
p2$Date <- as.Date(p2$Date)

p2 <- p2 %>% group_by(Date) %>% summarise("Pipe2 Records count"=n())

merge(p1,p2,by="Date")
```

##		Date	Pipe1	${\tt Records}$	count	Pipe2	${\tt Records}$	count
##	1	2015-10-23			96			23
##	2	2015-10-24			109			24
##	3	2015-10-25			95			24
##	4	2015-10-26			118			24
##	5	2015-10-27			99			24
##	6	2015-10-28			104			24
##	7	2015-10-29			96			24
##	8	2015-10-30			111			24
##	9	2015-10-31			91			24
##	10	2015-11-01			81			24

It is evident here that pipe1 dataset has an uneven count distribution for given date while pipe2 has even count daily.

Data Cleaning

In this step we will make pipe1 data evenly distributed (per hour) for every day. We will take mean of records per hour and then recreate the Date Time column. Nest we will do the same count comparison that was done earlier and check number of records per day.

```
pipe1.data <- pipe1.data %>%
  mutate(Date=date(`Date Time`), Hour=hour(`Date Time`)) %>%
  group_by(Date, Hour) %>%
  summarise(WaterFlow=mean(WaterFlow)) %>%
  ungroup() %>%
  mutate(`Date Time`=ymd_h(paste(Date, Hour))) %>%
  select(`Date Time`, WaterFlow)
```

```
## `summarise()` has grouped output by 'Date'. You can override using the `.groups` argument.
p1 <- pipe1.data
p1$Date <- ymd_hms(p1$`Date Time`)</pre>
```
